

2.08

Static and dynamic were two types of loads

Dead load - everything that's not move

Static load - apply to the building until reach maximum height.

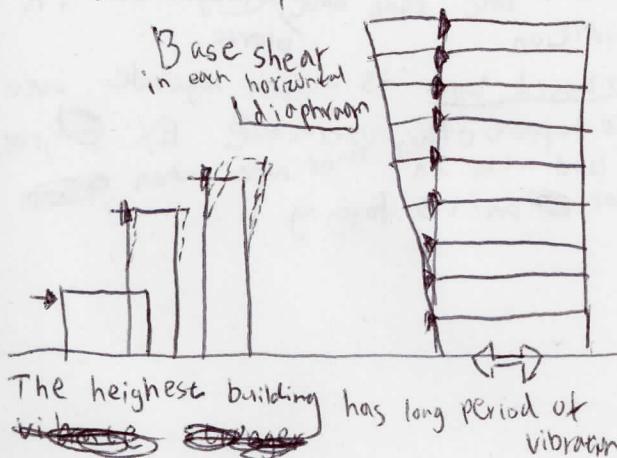

Dynamic loads - has rapid changes in magnitude and point of application

2.09

- wind loads are coming from any horizontal direction
- The amount of wind loads depend on the area of the building
- able to resist any opposite direction
- minimum design value of wind pressure were 10 m
- Design values increase based on how big the building was

2.10

- Horizontal components is one of the difficult part in design because of the ground motion

The highest building has long period of vibration
