We have already seen that we may reduce fractions if the numerator and denominator have the same factor.

$$\frac{15}{6} = \frac{5 \cdot 3}{2 \cdot 3} = \frac{5}{2}$$
$$\frac{(x-2)(3x-4)}{2(3x-4)} = \frac{x-2}{2} = \frac{x}{2} - \frac{2}{2} = \frac{x}{2} - 1$$

Writing a polynomial as a product of other polynomials (of smaller degree) is the key to reducing fractions. Writing polynomials in such a way is called **factoring**.

2/13

Earlier we multiplied factors together to get a product. Now, we will reverse this process; we will start with a product and then break it down into its factors. Splitting a product into factors is called **factoring**.

- If we write a polynomial P as a product of polynomials, we say that we have factored P.
- A polynomial F is a factor of P if we can write P as P = F · G for some polynomial G.
- The greatest common factor (GCF) of two or more monomials is a monomial F that satisfies the following conditions:
 - F is a factor of all the monomials, that is, F is a common factor, and
 - any other common factor of all the monomials is a factor of F.
- The greatest common factor (GCF) of a polynomial is the GCF of its terms.

While we say the greatest common factor, there are actually two: one with a positive coefficient and one with a negative coefficient. We use "factor" as both a noun and a verb.

ヘロト 人間ト ヘヨト ヘヨト

We summarize the steps we use to find the greatest common factor.

- Factor each coefficient into primes. Write all variables with exponents in expanded form.
- List all factors—matching common factors in a column. In each column, circle the common factors (this is suggested as a way of 'book-keeping').
- Sollect the factors (including repeats) that all polynomials share.
- Multiply the factors.

Examples:

- Find the greatest common factor of $21x^3$, $9x^2$, and 15x.
- Find the greatest common factor of $25m^4$, $35m^3$, and $20m^2$.

6/13

It is sometimes useful to represent a number as a product of factors. To do this we apply the Distributive Property "in reverse."

Distributive Property: If a, b and c are real numbers then

$$a(b+c) = ab+ac$$

and

$$ab + ac = a(b + c).$$

The form on the left is used to multiply. The form on the right is used to factor.

Factoring the Greatest Common Factor from a Polynomial

The procedure for factoring the GCF from a polynomial is as follows.

- I Find the GCF of all the terms of the polynomial.
- Rewrite each term as a product using the GCF.
- **③** Use the "reverse" Distributive Property to factor the polynomial.
- Oneck by multiplying the factors.

Factoring the Greatest Common Factor from a Polynomial

Examples: Factor out the GCF.

- $5x^3 25x^2$
- $6y^3 15y^2 + 12y$
- On Your Own: $8x^3y 20x^2y^2 + 12xy^3$

Image: A = 1 = 1

Factoring the Greatest Common Factor from a Polynomial

We can extend the idea of factoring out the GCF to a binomial.

Examples:Factor out the common factor of the two terms and check your answer.

•
$$2x(x-5) - 5(x-5)$$

• 8n(n+2) + 4(n+2)

Sometimes there is no common factor of all the terms of a polynomial. When there are four terms we separate the polynomial into two parts with two terms in each part. Then look for the GCF in each part. If the polynomial can be factored, you will find a common factor emerges from both parts. **Not all polynomials can be factored.**

Factoring by Grouping

- Group terms with common factors.
- Factor out the common factor in each group.
- Factor the common factor from the polynomial.
- Check by multiplying the factors.

Examples: Factor by grouping and check your answer.

•
$$xy + 8y + 3x + 24$$

- $x^2 + 2x 5x 10$
- *ab* + 7*b* + 8*a* + 56

Try the following problems on your own! Check your answers when possible.

- Factor. $36x^5 6x^3$
- Factor. 6x(y-8) 2(y-8)
- Factor by grouping. -18xy + 21x 30y + 35
- Factor by grouping. $10x^2 + 5x 4x 2$
