

An Introduction to Quantum Algorithms for MAT 2440

Marianna Bonanome
City Tech

April 18, 2019

Goals:

- 1 The “intellectual core” of computer science - review of computational complexity.
- 2 Classical key exchange protocols and RSA cryptosystems
- 3 Moving from the classical to the quantum
- 4 What is a quantum bit (qubit)?
- 5 Advantages of quantum computation vs. classical computation
- 6 Reversible logic Gates, quantum logic gates
- 7 Breaking RSA! - Shor’s algorithm for the quantum factorization of integers
- 8 What else can we do? Grover’s search procedure.
- 9 Conclusions and where are we headed?
- 10 References

Computational Complexity - Hard, Harder, Hardest

Efficient Algorithms

Some polynomial time algorithms we learned about this semester:

- 1 The linear search procedure:

Computational Complexity - Hard, Harder, Hardest

Efficient Algorithms

Some polynomial time algorithms we learned about this semester:

- 1 The linear search procedure: $\Theta(n)$.
- 2 The bubble sort procedure:

Computational Complexity - Hard, Harder, Hardest

Efficient Algorithms

Some polynomial time algorithms we learned about this semester:

- 1 The linear search procedure: $\Theta(n)$.
- 2 The bubble sort procedure: $\Theta(n^2)$.
- 3 Matrix multiplication:

Computational Complexity - Hard, Harder, Hardest

Efficient Algorithms

Some polynomial time algorithms we learned about this semester:

- 1 The linear search procedure: $\Theta(n)$.
- 2 The bubble sort procedure: $\Theta(n^2)$.
- 3 Matrix multiplication: $\Theta(n^3)$.

Tractability

A problem that is solvable using an algorithm with polynomial (or better) worst-complexity is called **tractable**, because the expectation is that the algorithm will produce the solution to the problem for reasonably sized input in a relatively short time.

- 3 Matrix multiplication: $\Theta(n^3)$.

Tractability

A problem that is solvable using an algorithm with polynomial (or better) worst-complexity is called **tractable**, because the expectation is that the algorithm will produce the solution to the problem for reasonably sized input in a relatively short time.

Problems that cannot be solved using an algorithm with worst-case polynomial time complexity are called **intractable**.

Some important classes of problems

P and NP

The class problems which are tractable is denoted by P .

Some important classes of problems

P and NP

The class problems which are tractable is denoted by P .

There are many problems for for which a solution, once found, can be recognized as correct in polynomial time - even though the solution itself might be hard to find (no poly-time algorithm to find the solution). The class of these problems is referred to as NP .

Some important classes of problems

P and NP

The class problems which are tractable is denoted by P .

There are many problems for for which a solution, once found, can be recognized as correct in polynomial time - even though the solution itself might be hard to find (no poly-time algorithm to find the solution). The class of these problems is referred to as NP .

A familiar NP problem

The factoring problem is in NP but outside of P because no known algorithm for a classical computer can solve it in only a polynomial number of steps - instead the number of steps increases exponentially as n increases. We will come back to this problem later!

A familiar NP problem

The factoring problem is in NP but outside of P because no known algorithm for a classical computer can solve it in only a polynomial number of steps - instead the number of steps increases exponentially as n increases. We will come back to this problem later!

NP-complete

There is a class of problems with the property that if any of these problems can be solved by a an efficient algorithm, then all problems in the class can be solved by an efficient algorithm. They are in essence the “same” problem!!!

Examples of **NP-complete** problems

- 1 Given the dimensions of various boxes and want a way to pack them in your trunk.

Examples of **NP-complete** problems

- 1 Given the dimensions of various boxes and want a way to pack them in your trunk.
- 2 Given a map, color each country red, blue or green so that no two neighboring countries are the same.

Examples of NP-complete problems

- 1 Given the dimensions of various boxes and want a way to pack them in your trunk.
- 2 Given a map, color each country red, blue or green so that no two neighboring countries are the same.
- 3 Given a list of island connected by bridges and you want a tour which visits each island exactly once. If you want to find the shortest route, then this is known as the “Traveling Salesperson Problem.”

Examples of NP-complete problems

- 1 Given the dimensions of various boxes and want a way to pack them in your trunk.
- 2 Given a map, color each country red, blue or green so that no two neighboring countries are the same.
- 3 Given a list of island connected by bridges and you want a tour which visits each island exactly once. If you want to find the shortest route, then this is known as the “Traveling Salesperson Problem.”
- 4 Every known algorithm for these problems will take an amount of time that increases **exponentially** with the problem size.

Examples of NP-complete problems

- 1 Given the dimensions of various boxes and want a way to pack them in your trunk.
- 2 Given a map, color each country red, blue or green so that no two neighboring countries are the same.
- 3 Given a list of island connected by bridges and you want a tour which visits each island exactly once. If you want to find the shortest route, then this is known as the “Traveling Salesperson Problem.”
- 4 Every known algorithm for these problems will take an amount of time that increases **exponentially** with the problem size.
- 5 These are all the “same” in that an efficient algorithm for solving one of them will imply an efficient algorithm for solving all of them.

$P = NP?$

The million dollar question (**literally**)

An efficient algorithm for an **NP -complete** problem would mean that computer scientists' present picture of the classes P , NP and **NP -complete** was utterly wrong!!! It would mean that $P = NP!$

$P = NP?$

The million dollar question (**literally**)

An efficient algorithm for an **NP -complete** problem would mean that computer scientists' present picture of the classes P , NP and **NP -complete** was utterly wrong!!! It would mean that $P = NP$!

Does such an algorithm exist? This question carries a \$1,000,000 reward from the Clay Math Institute in Cambridge, Mass.

$P = NP?$

The million dollar question (**literally**)

An efficient algorithm for an **NP -complete** problem would mean that computer scientists' present picture of the classes P , NP and **NP -complete** was utterly wrong!!! It would mean that $P = NP$!

Does such an algorithm exist? This question carries a \$1,000,000 reward from the Clay Math Institute in Cambridge, Mass.

If we grant that $P \neq NP$, our only hope is to broaden what we mean by "computer."

$P = NP?$

The million dollar question (**literally**)

An efficient algorithm for an **NP -complete** problem would mean that computer scientists' present picture of the classes P , NP and **NP -complete** was utterly wrong!!! It would mean that $P = NP$!

Does such an algorithm exist? This question carries a \$1,000,000 reward from the Clay Math Institute in Cambridge, Mass.

If we grant that $P \neq NP$, our only hope is to broaden what we mean by "computer."

NOTE: The factoring problem is neither known nor believed to be **NP -complete**.

RSA cryptosystems

In the RSA (Rivest, Shamir and Adleman) cryptosystem, each individual has an encryption key (n, e) where $n = pq$ the modulus is the product of two large primes p and q , (say with 200 digits each), and an exponent e that is relatively prime to $(p - 1)(q - 1)$

RSA cryptosystems

In the RSA (Rivest, Shamir and Adleman) cryptosystem, each individual has an encryption key (n, e) where $n = pq$ the modulus is the product of two large primes p and q , (say with 200 digits each), and an exponent e that is relatively prime to $(p - 1)(q - 1)$

To encrypt a message, translate the text to numerical equivalents, break into blocks m_i , and then use fast modular exponentiation to compute they encrypted blocks c_i using the function $c_i = m_i^e \pmod n$.

In the RSA (Rivest, Shamir and Adleman) cryptosystem, each individual has an encryption key (n, e) where $n = pq$ the modulus is the product of two large primes p and q , (say with 200 digits each), and an exponent e that is relatively prime to $(p - 1)(q - 1)$

To encrypt a message, translate the text to numerical equivalents, break into blocks m_i , and then use fast modular exponentiation to compute they encrypted blocks c_i using the function $c_i = m_i^e \pmod n$.

In order to *decrypt* a message sent in this scheme, one must be able to find the decryption key d which is the inverse of e , $\pmod{(p - 1)(q - 1)}$. Without knowing p and q , and only knowing n (with possibly 400 digits), this system is difficult to break!

Shifting focus: Classical to Quantum

Limits to Digital Computation

In 1965 Gordon Moore gave a law for the growth of computing power which states

Shifting focus: Classical to Quantum

Limits to Digital Computation

In 1965 Gordon Moore gave a law for the growth of computing power which states

Moore's Law

Computer power will double for constant cost roughly every two years.

Moore's Law

Computer power will double for constant cost roughly every two years.

Prediction

This dream will come to an end during this decade.

Quantum effects are beginning to interfere with electronic devices as they are made smaller and smaller.

Solution

Move to a different paradigm!

Solution

Move to a different paradigm!

Can we use the counterintuitive laws of quantum mechanics to our advantage?

Solution

Move to a different paradigm!

Can we use the counterintuitive laws of quantum mechanics to our advantage?

Yes! In 1982 Richard Feynman and Paul Benioff independently observed that a quantum system can perform a computation.

Solution

Move to a different paradigm!

Can we use the counterintuitive laws of quantum mechanics to our advantage?

Yes! In 1982 Richard Feynman and Paul Benioff independently observed that a quantum system can perform a computation.

In 1985 David Deutsch defined quantum Turing machines, a theoretical model for quantum computing.

What is a qubit?

A quantum bit, or “qubit” stores information.

What is a qubit?

A quantum bit, or “qubit” stores information. Physically

- A qubit can be an ion which can occupy different quantum states. The atom in the ground state corresponds to the value “0” and the excited state, “1”.

What is a qubit?

A quantum bit, or “qubit” stores information. Physically

- A qubit can be an ion which can occupy different quantum states. The atom in the ground state corresponds to the value “0” and the excited state, “1”.
- A qubit can be a spin $\frac{1}{2}$ particle which can be in the spin up (“0”) or spin down (“1”) state.

What is a qubit?

How is a qubit different from a regular bit?

Qubits exist in a continuum of states between 0 and 1 (superposition) until they are observed.

How is a qubit different from a regular bit?

Qubits exist in a continuum of states between 0 and 1 (superposition) until they are observed.

$$|\Psi\rangle = \alpha_0|0\rangle + \alpha_1|1\rangle \text{ where } |\alpha_0|^2 + |\alpha_1|^2 = 1$$

How is a qubit different from a regular bit?

Qubits exist in a continuum of states between 0 and 1 (superposition) until they are observed.

$$|\Psi\rangle = \alpha_0|0\rangle + \alpha_1|1\rangle \text{ where } |\alpha_0|^2 + |\alpha_1|^2 = 1$$

We can generalize the concept of qubits to quantum registers. A state of a quantum register of size n is a *tensor product* of n qubits and can be written as

$$|\Psi\rangle = \sum_{x \in \{0,1\}^n} \alpha_x |x\rangle$$

where

$$\sum_{x \in \{0,1\}^n} |\alpha_x|^2 = 1$$

How is a qubit different from a regular bit?

Qubits exist in a continuum of states between 0 and 1 (superposition) until they are observed.

We can generalize the concept of qubits to quantum registers. A state of a quantum register of size n is a *tensor product* of n qubits and can be written as

$$|\Psi\rangle = \sum_{x \in \{0,1\}^n} \alpha_x |x\rangle$$

where

$$\sum_{x \in \{0,1\}^n} |\alpha_x|^2 = 1$$

The size of the computational state space of a quantum register is exponential in the physical size of the system.

How can a cat be both dead and alive?

How can a cat be both dead and alive?

What is the main advantage of quantum computation over digital computation?

- In 1985 David Deutsch found the quantum parallelism principle. This principle allows one to evaluate a function f for distinct inputs simultaneously.

What is the main advantage of quantum computation over digital computation?

- In 1985 David Deutsch found the quantum parallelism principle. This principle allows one to evaluate a function f for distinct inputs simultaneously.
- Quantum parallelism exploits the superposition of states.

Reversible Logic Gates

- In 1961 Landauer showed that the only logical operations that require dissipation of energy are irreversible ones.

Reversible Logic Gates

- In 1961 Landauer showed that the only logical operations that require dissipation of energy are irreversible ones.
- Logic gates are typically irreversible.

Reversible Logic Gates

- In 1961 Landauer showed that the only logical operations that require dissipation of energy are irreversible ones.
- Logic gates are typically irreversible.
- The AND-gate is obviously irreversible since given the output $a_f = 0$ we cannot say if the input (a_i, b_i) is equal to $(0, 0)$, $(0, 1)$ or $(1, 0)$.

Reversible Logic Gates

- In 1961 Landauer showed that the only logical operations that require dissipation of energy are irreversible ones.
- Logic gates are typically irreversible.
- The AND-gate is obviously irreversible since given the output $a_f = 0$ we cannot say if the input (a_i, b_i) is equal to $(0, 0)$, $(0, 1)$ or $(1, 0)$.
- The same is true for the OR, XOR, or NOR-gates.

Reversible Logic Gates

- In 1961 Landauer showed that the only logical operations that require dissipation of energy are irreversible ones.
- Logic gates are typically irreversible.
- The AND-gate is obviously irreversible since given the output $a_f = 0$ we cannot say if the input (a_i, b_i) is equal to $(0, 0)$, $(0, 1)$ or $(1, 0)$.
- The same is true for the OR, XOR, or NOR-gates.
- In 1973 Bennett found that any computation can be performed using only reversible steps.

Example

The following is the truth table for the three-bit CONTROL-CONTROL-NOT gate (or CCN-gate).

a_i	b_i	c_i
0	0	0
0	0	1
0	1	0
0	1	1
1	0	0
1	0	1
1	1	0
1	1	1

Example

The following is the truth table for the three-bit CONTROL-CONTROL-NOT gate (or CCN-gate).

a_i	b_i	c_i
0	0	0
0	0	1
0	1	0
0	1	1
1	0	0
1	0	1
1	1	0
1	1	1

a_f	b_f	c_f
0	0	0
0	0	1
0	1	0
0	1	1
1	0	0
1	0	1
1	1	1
1	1	0

Quantum Logic Gates

- Why are they reversible?

Quantum Logic Gates

- Why are they reversible?
- Both classical and quantum mechanics in the Hamiltonian formulation describe only reversible processes.

Quantum Logic Gates

- Why are they reversible?
- Both classical and quantum mechanics in the Hamiltonian formulation describe only reversible processes.
- Quantum logic gates generally act on a superposition of digital states. They can be represented by operators (matrices).

Quantum Logic Gates

- Why are they reversible?
- Both classical and quantum mechanics in the Hamiltonian formulation describe only reversible processes.
- Quantum logic gates generally act on a superposition of digital states. They can be represented by operators (matrices).
- Unitary matrices represent the time evolution of quantum mechanical systems.

Quantum Logic Gates

- Why are they reversible?
- Both classical and quantum mechanics in the Hamiltonian formulation describe only reversible processes.
- Quantum logic gates generally act on a superposition of digital states. They can be represented by operators (matrices).
- Unitary matrices represent the time evolution of quantum mechanical systems.
- So quantum logic gates can be represented by unitary matrices.

The Quantum N-gate

$$N = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

transforms $|0\rangle \rightarrow |1\rangle$ and $|1\rangle \rightarrow |0\rangle$.

Quantum Circuits

The quantum circuit in the figure below accomplishes the task of exchanging the state of the two input bits. Starting out with the state $|a, b\rangle$

Quantum Circuits

Shor's Algorithm is a quantum algorithm that factors an integer in polynomial time (1994). If the integer has L digits, Shor's algorithm takes $O(L^2)$ to factor it.

Shor's Algorithm is a quantum algorithm that factors an integer in polynomial time (1994). If the integer has L digits, Shor's algorithm takes $O(L^2)$ to factor it.

Why should we care?

- We have studied the RSA cryptosystem and we have seen that the security of the system is based on the practical difficulty of factoring the product of two large prime numbers, the factoring problem.

Shor's Algorithm is a quantum algorithm that factors an integer in polynomial time (1994). If the integer has L digits, Shor's algorithm takes $O(L^2)$ to factor it.

Why should we care?

- We have studied the RSA cryptosystem and we have seen that the security of the system is based on the practical difficulty of factoring the product of two large prime numbers, the factoring problem.
- For instance, RSA-768, the largest number to be factored to date, had 232 decimal digits and was factored over multiple years ending in 2009, using the equivalent of almost 2000 years of computing on a single 2.2 GHz AMD Opteron processor with 2GB RAM.2!

See https://en.wikipedia.org/wiki/RSA_numbers

Why should we care?

- We have studied the RSA cryptosystem and we have seen that the security of the system is based on the practical difficulty of factoring the product of two large prime numbers, the factoring problem.
- For instance, RSA-768, the largest number to be factored to date, had 232 decimal digits and was factored over multiple years ending in 2009, using the equivalent of almost 2000 years of computing on a single 2.2 GHz AMD Opteron processor with 2GB RAM.2!

See https://en.wikipedia.org/wiki/RSA_numbers

- On a classical computer the best known method for factorization of a number with 300 digits takes $5 \cdot 10^{24}$ steps or with terahertz speed **150,000 years!**

Shor's Algorithm

Shor's algorithm hinges on being able to quickly compute the period of the following periodic function (using a quantum algorithm):

$$f(x) = y^x \pmod{n}$$

for $x = 0, 1, 2, \dots$. Where $n = pq$, p and q prime factors.

To begin, select y randomly so that $1 < y < n$ and $(y, n) = 1$. Next, find the period T of the function $f(x) = y^x \pmod{n}$. Compute $z = y^{T/2}$. Lastly, to find factors of n , compute $(z + 1, n)$ and $(z - 1, n)$ (can use the Euclidean Algorithm).

Shor's Algorithm: An example

Factoring $n = 30$ using Shor's Algorithm

- Given $n = 30$, choose a y , so that $1 < y < 30$ and $(y, 30) = 1$. I will use $y = 11$ (but I could have chosen: 19, 29, 7, 13 or 23).
- Compute values of $f(x)$ to find the period of $f(x)$ (by hand):

$$f(0) = 11^0 \pmod{30} = 1$$

$$f(1) = 11^1 \pmod{30} = 11$$

$$f(2) = 11^2 \pmod{30} = 1$$

$$f(3) = 11^3 \pmod{30} = 11$$

$$f(4) = 11^4 \pmod{30} = 1 \dots$$

- T is obvious 2. Now compute $z = y^{T/2} = 11^{2/2} = 11^1 = 11$.
- Finally factors of $n = 30$ are $(z + 1, 30) = (12, 30) = 6$ and $(z - 1, 30) = (10, 30) = 10$. Both 6 and 10 are factors of 30.

Some notes:

- This factoring method fails sometimes, for instance, when the period T is odd. HOWEVER,

Some notes:

- This factoring method fails sometimes, for instance, when the period T is odd. HOWEVER,
- If y ($1 < y < n$) is randomly selected, Ekert and Jozsa showed that the probability that two numbers have $gcd = 1$ is greater than $1/\log_2(n)$ so the probability of failure is small. See <https://doi.org/10.1103/RevModPhys.68.733>.

Some notes:

- This factoring method fails sometimes, for instance, when the period T is odd. HOWEVER,
- If y ($1 < y < n$) is randomly selected, Ekert and Jozsa showed that the probability that two numbers have $gcd = 1$ is greater than $1/\log_2(n)$ so the probability of failure is small. See <https://doi.org/10.1103/RevModPhys.68.733>.
- Also note, that for $y = 11, 19, \text{ and } 29$, $T = 2$ and for $y = 7, 13, \text{ and } 23$, $T = 4$.

Your turn to try!

Use Shor's algorithm to factor $n = 21$. You may use our Python code for fast modular exponentiation to help you find the period of $f(x)$ and the code for computing the gcd if you would like.

The Quantum Search Algorithm

- In 1996 Lov K. Grover gave a quantum algorithm for searching an unsorted list with N entries.

The Quantum Search Algorithm

- In 1996 Lov K. Grover gave a quantum algorithm for searching an unsorted list with N entries.
- By having the input and output in superpositions of states one can find an object in $O(N^{1/2})$ quantum mechanical steps instead of $O(N)$ classical steps for the worst-case linear search.

The Quantum Search Algorithm

- In 1996 Lov K. Grover gave a quantum algorithm for searching an unsorted list with N entries.
- By having the input and output in superpositions of states one can find an object in $O(N^{1/2})$ quantum mechanical steps instead of $O(N)$ classical steps for the worst-case linear search.

Suppose one wants to search through N elements, indexed $0, 1, 2, \dots, N - 1$.

The Quantum Search Algorithm

- In 1996 Lov K. Grover gave a quantum algorithm for searching an unsorted list with N entries.
- By having the input and output in superpositions of states one can find an object in $O(N^{1/2})$ quantum mechanical steps instead of $O(N)$ classical steps for the worst-case linear search.

Suppose one wants to search through N elements, indexed $0, 1, 2, \dots, N - 1$.

Assume $N = 2^n$ so the index is stored in n bits and that the search problem has one solution.

The Quantum Search Algorithm

- In 1996 Lov K. Grover gave a quantum algorithm for searching an unsorted list with N entries.
- By having the input and output in superpositions of states one can find an object in $O(N^{1/2})$ quantum mechanical steps instead of $O(N)$ classical steps for the worst-case linear search.

Suppose one wants to search through N elements, indexed $0, 1, 2, \dots, N - 1$.

Assume $N = 2^n$ so the index is stored in n bits and that the search problem has one solution.

Define a function $f(x)$, such that for $x \in \{0, 1, \dots, N - 1\}$

$$f(x) = \begin{cases} 0 & \text{if } x \text{ is not a solution} \\ 1 & \text{if } x \text{ is a solution.} \end{cases}$$

An oracle is supplied which has the ability to recognize the solutions for the search problem. Recognition is signalled by the use of an oracle qubit $|q\rangle$.

An oracle is supplied which has the ability to recognize the solutions for the search problem. Recognition is signalled by the use of an oracle qubit $|q\rangle$.

The oracle, O , is a unitary operator defined on the computational basis $|0\rangle, |1\rangle$.

The action of the oracle is

$$O|x\rangle|q\rangle = |x\rangle|q \oplus f(x)\rangle$$

where x is the index register and $|q\rangle$ is the oracle qubit.

In order to achieve the correct solution with probability near 1, one must apply the Grover iteration $O\left(\sqrt{N}\right)$ times if there is a single solution.

Boyer, Brassard, Høyer and Tapp showed that if it is known in advance that there are M solutions to the search problem, one must apply the Grover iteration $O\left(\sqrt{\frac{N}{M}}\right)$ times.

Geometric Visualization

One can view the Grover iteration as a rotation in the two dimensional Hilbert space spanned by the initial vector $|\psi\rangle$ and the state that consists of the superposition of the solutions to the search problem.

Geometric Visualization

One can view the Grover iteration as a rotation in the two dimensional Hilbert space spanned by the initial vector $|\psi\rangle$ and the state that consists of the superposition of the solutions to the search problem.

- Let the notation \sum_x' indicate the sum over all the x which are solutions to the search problem.

One can view the Grover iteration as a rotation in the two dimensional Hilbert space spanned by the initial vector $|\psi\rangle$ and the state that consists of the superposition of the solutions to the search problem.

- Let the notation \sum_x' indicate the sum over all the x which are solutions to the search problem.
- Let \sum_x'' indicate the sum over all the x which are not solutions.

Then one can describe the following two states:

- $|\alpha\rangle = \frac{1}{\sqrt{N-M}} \sum_x'' |x\rangle$ and

Geometric Visualization

One can view the Grover iteration as a rotation in the two dimensional Hilbert space spanned by the initial vector $|\psi\rangle$ and the state that consists of the superposition of the solutions to the search problem.

- Let the notation \sum_x' indicate the sum over all the x which are solutions to the search problem.
- Let \sum_x'' indicate the sum over all the x which are not solutions.

Then one can describe the following two states:

- $|\alpha\rangle = \frac{1}{\sqrt{N-M}} \sum_x'' |x\rangle$ and
- $|\beta\rangle = \frac{1}{\sqrt{M}} \sum_x' |x\rangle$

Figure: The action of a single Grover iteration G .

- No matter how many times G is applied to $|\psi\rangle$, the vector remains in the plane spanned by $|\alpha\rangle$ and $|\beta\rangle$.

Figure: The action of a single Grover iteration G .

- No matter how many times G is applied to $|\psi\rangle$, the vector remains in the plane spanned by $|\alpha\rangle$ and $|\beta\rangle$.
- In fact, one also knows the angle of rotation since $\cos\left(\frac{\theta}{2}\right) = \sqrt{\frac{(N-M)}{N}}$.

Figure: The action of a single Grover iteration G .

- No matter how many times G is applied to $|\psi\rangle$, the vector remains in the plane spanned by $|\alpha\rangle$ and $|\beta\rangle$.
- In fact, one also knows the angle of rotation since $\cos\left(\frac{\theta}{2}\right) = \sqrt{\frac{(N-M)}{N}}$.
- Each application of G rotates the vector $|\psi\rangle$ closer to alignment with the vector $|\beta\rangle$.

Figure: The action of a single Grover iteration G .

- No matter how many times G is applied to $|\psi\rangle$, the vector remains in the plane spanned by $|\alpha\rangle$ and $|\beta\rangle$.
- In fact, one also knows the angle of rotation since $\cos\left(\frac{\theta}{2}\right) = \sqrt{\frac{(N-M)}{N}}$.
- Each application of G rotates the vector $|\psi\rangle$ closer to alignment with the vector $|\beta\rangle$.
- When this occurs, a measurement in the computational basis produces one of the outcomes superimposed on $|\beta\rangle$ with high probability.
- This is a solution to the search problem.

Conclusions:

- Until today there are only two basic quantum algorithmic methods known.
 - ▶ **Shor's Algorithm** for the factorization of integers.

Conclusions:

- Until today there are only two basic quantum algorithmic methods known.
 - ▶ **Shor's Algorithm** for the factorization of integers.
 - ▶ **Grover's Search Algorithm.**

Conclusions:

- Until today there are only two basic quantum algorithmic methods known.
 - ▶ **Shor's Algorithm** for the factorization of integers.
 - ▶ **Grover's Search Algorithm.**
- Quantum algorithms have the potential to demonstrate that for some problems quantum computation is more efficient than classical computation.

Conclusions:

- Until today there are only two basic quantum algorithmic methods known.
 - ▶ **Shor's Algorithm** for the factorization of integers.
 - ▶ **Grover's Search Algorithm.**
- Quantum algorithms have the potential to demonstrate that for some problems quantum computation is more efficient than classical computation.
- A goal is to determine for which problems quantum computers are faster than classical computers.

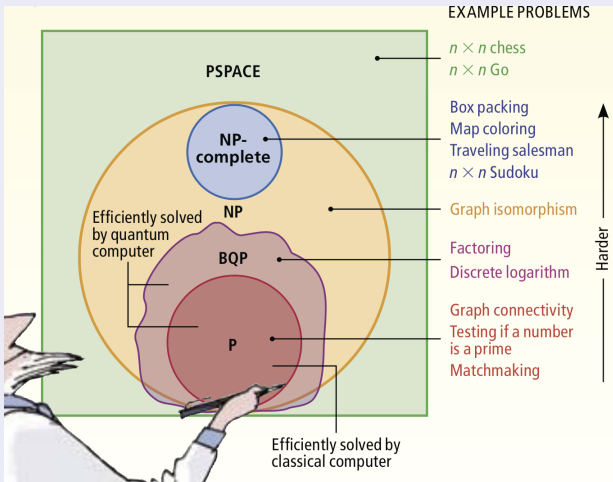

Conclusions:

- Until today there are only two basic quantum algorithmic methods known.
 - ▶ **Shor's Algorithm** for the factorization of integers.
 - ▶ **Grover's Search Algorithm.**
- Quantum algorithms have the potential to demonstrate that for some problems quantum computation is more efficient than classical computation.
- A goal is to determine for which problems quantum computers are faster than classical computers.
- Two important quantum complexity classes are BQP and QMA which are the bounded-error quantum analogues of P and NP.

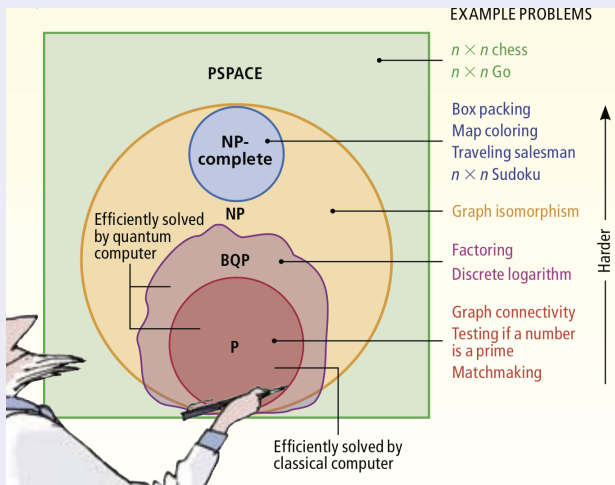

Conclusions:

- Until today there are only two basic quantum algorithmic methods known.

 - ▶ **Grover's Search Algorithm.**
- Quantum algorithms have the potential to demonstrate that for some problems quantum computation is more efficient than classical computation.
- A goal is to determine for which problems quantum computers are faster than classical computers.
- Two important quantum complexity classes are BQP and QMA which are the bounded-error quantum analogues of P and NP.
- Goal: Find out where these classes lie with respect to classical complexity classes such as P, NP, PP (problems solvable by probabilistic Turing machine in poly-time), PSPACE (problems that can be solved by a Turing machine using a poly-space) and other complexity classes.

Our best guess:

Our best guess:

The diagram depicts the class of problems a quantum computer would solve efficiently, BQP ("bounded error, probabilistic, polynomial time"), might relate to other fundamental classes of computational problems.

Timeline:

● 1998

- ▶ First working 3-qubit Nuclear Magnetic Resonance (NMR) computer.
- ▶ First execution of Grover's algorithm on an NMR computer.

● 2000

- ▶ First working 5-qubit NMR computer demonstrated at the Technical University of Munich.
- ▶ First execution of order finding (part of Shor's algorithm) at IBM's Almaden Research Center and Stanford University.
- ▶ First working 7-qubit NMR computer demonstrated at the Los Alamos National Laboratory.

● 2001

- ▶ First execution of Shor's algorithm at IBM's Almaden Research Center and Stanford University. The number 15 was factored.

- **2006**

- ▶ First 12 qubit quantum computer benchmarked at the Institute for Quantum Computing (IQC) and PI in Waterloo.

- **2008**

- ▶ D-Wave Systems claims to have working 28-qubit quantum computer.

- **2009**

- ▶ Google collaborates with D-Wave Systems on image search technology using quantum computing.

● 2010

- ▶ D-Wave claims to have developed quantum annealing and introduces their product called D-Wave One. The company claims this is the first commercially available quantum computer.
- ▶ Practical error rates achieved.

● 2012

- ▶ Physicists Create a Working Transistor From a Single Atom.
- ▶ D-Wave claims a quantum computation using 84 qubits.

● 2013

- ▶ Documents leaked by Edward Snowden revealed that the NSA worked to "Insert vulnerabilities into commercial encryption systems, IT systems, networks, and endpoint communications devices used by targets" as part of the Bullrun program.

● 2014

- ▶ Documents leaked by Edward Snowden also confirm the Penetrating Hard Targets project, by which the NSA seeks to develop a quantum computing capability for cryptography purposes.

● 2015

- ▶ Quantum error detection code using a square lattice of four superconducting qubits.
- ▶ D-Wave Systems Inc. announced on 22 June that it had broken the 1000 qubit barrier.

● 2016

- ▶ Google, using an array of 9 superconducting qubits developed by the Martinis group and UCSB, accurately simulates a hydrogen molecule.

• 2017

- ▶ D-Wave Systems Inc. announced on 24 January general commercial availability of the D-Wave 2000Q quantum annealer, with 2000 qubits.
- ▶ Working blueprint for a microwave trapped ion quantum computer published in Science Advances by international collaborators.
- ▶ IBM unveils 17-qubit quantum computer and a better way of benchmarking it.

• 2018

- ▶ In late 2017 and early 2018 IBM, Intel, and Google each reported testing quantum processors containing 50, 49, and 72 qubits, respectively, all realized using superconducting circuits.
- ▶ In July 2018, a team led by the University of Sydney has achieved the world's first multi-qubit demonstration of a quantum chemistry calculation performed on a system of trapped ions, one of the leading hardware platforms in the race to develop a universal quantum computer.

Thank you!
